

RiversEdge West Riparian Restoration Conference
5 February 2019

Use of remote sensing to assess vegetation structure and model riparian wildlife habitat suitability: examples from the Santa Clara River, California

Bruce K. Orr, Stillwater Sciences

Thomas L. Dudley, U.C. Santa Barbara

James R. Hatten, U.S. Geological Survey

Linnea S. Hall, Western Foundation of Vertebrate Zoology

Rafael Real de Asua, Stillwater Sciences

In partnership with USFWS and CDFW

Overview

- LIDAR basics
- Background on the Santa Clara River
- Riparian birds and satellite models for habitat suitability
- LIDAR: topography and relative elevation
- Vegetation structure
 - Canopy height
 - Vertical structure (ground surface to top of canopy)
- Next steps

Airborne Laser Scanning (LIDAR) System Components

- Active sensor emits 40,000 – 150,000 infrared laser pulses per second
- Differentially-corrected GPS
- Inertial measurement unit (IMU)
- Computer to control the system monitor mission progress
- Interesting targets

Airborne Laser Scanning (LIDAR) Technology

- Acquires 1-5 reflections (returns) per pulse
- Typically 1 -10 measurements per m^2 or 4,000 – 40,000 measurements per acre
- Data delivered as XYZ points in a “data cloud”
- **Direct measurement of 3-D structure**
 - Terrain
 - Forest vegetation
 - Infrastructure

LIDAR-derived Bare-Earth Surface Model

Santa Clara River Case Study

Regional Overview – Southern California Coastal Watersheds

Santa Clara River and tributaries are a biodiversity hotspot:

- Still in predominantly natural state
- Home to many disappearing animals and plants
- Some of the last major riparian wetlands in Southern California
- Home to 18 Threatened & Endangered Species

FLOOD DYNAMICS

- Vegetation infilling (encroachment) during drier periods between major floods

FLOOD DYNAMICS

- Vegetation scour and reset after large floods, particularly in El Niño years

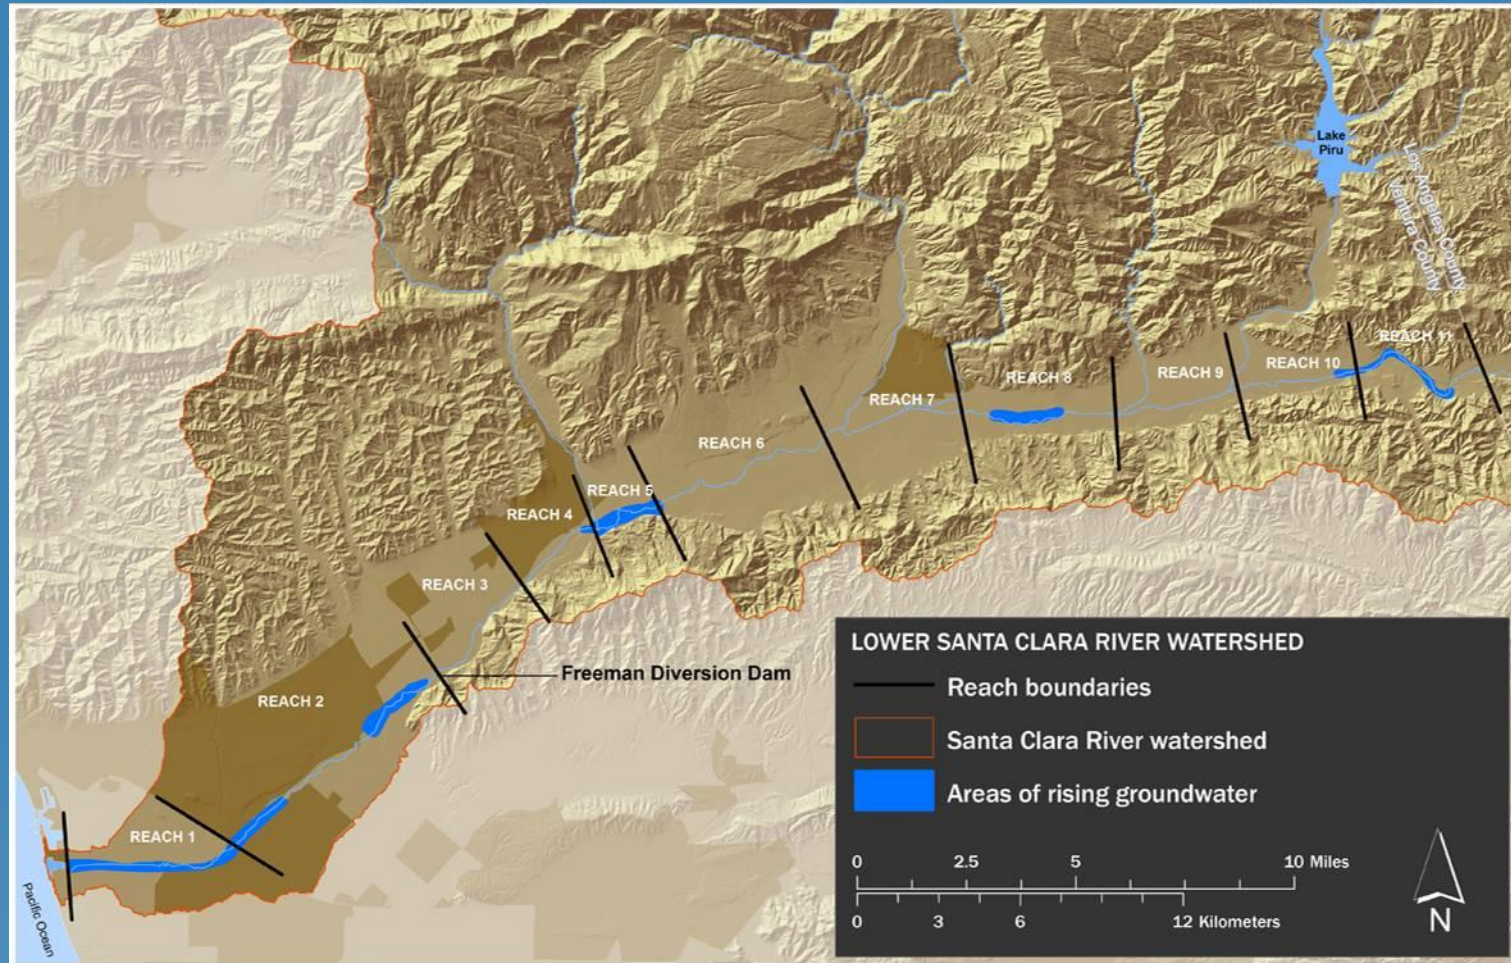

FLOOD DYNAMICS

- Rapid vegetation response after large resetting floods

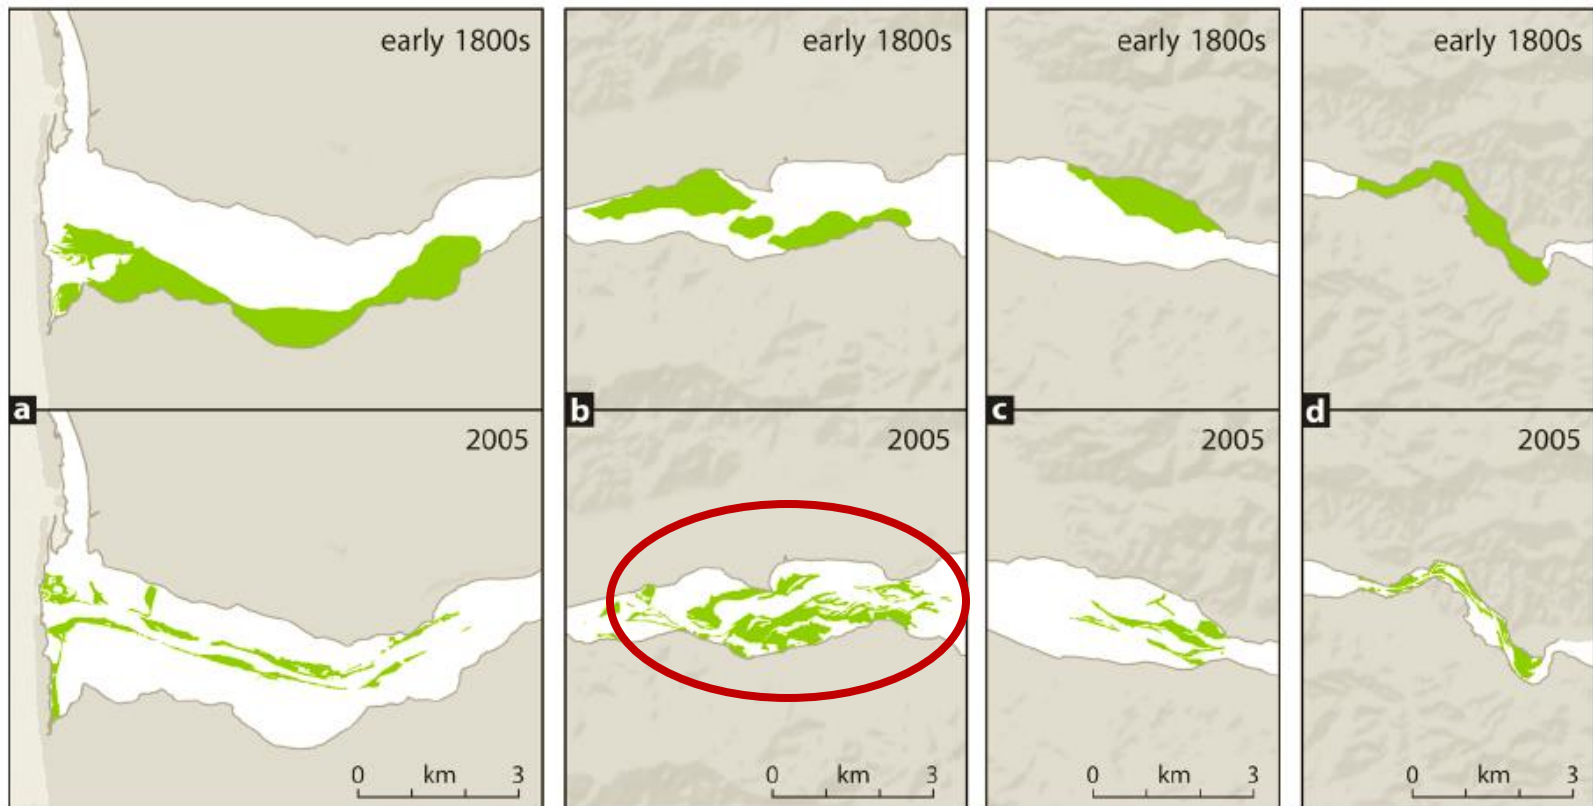

GROUNDWATER AVAILABILITY

➤ Gaining vs. losing reaches

FROM PAST PATTERNS TO FUTURE POTENTIAL

Notable Species on the SCR... The Big 5

➤ **Least Bell's Vireo** : ~ 500 breeding pairs

➤ **Yellow Warbler**: 1000s of pairs

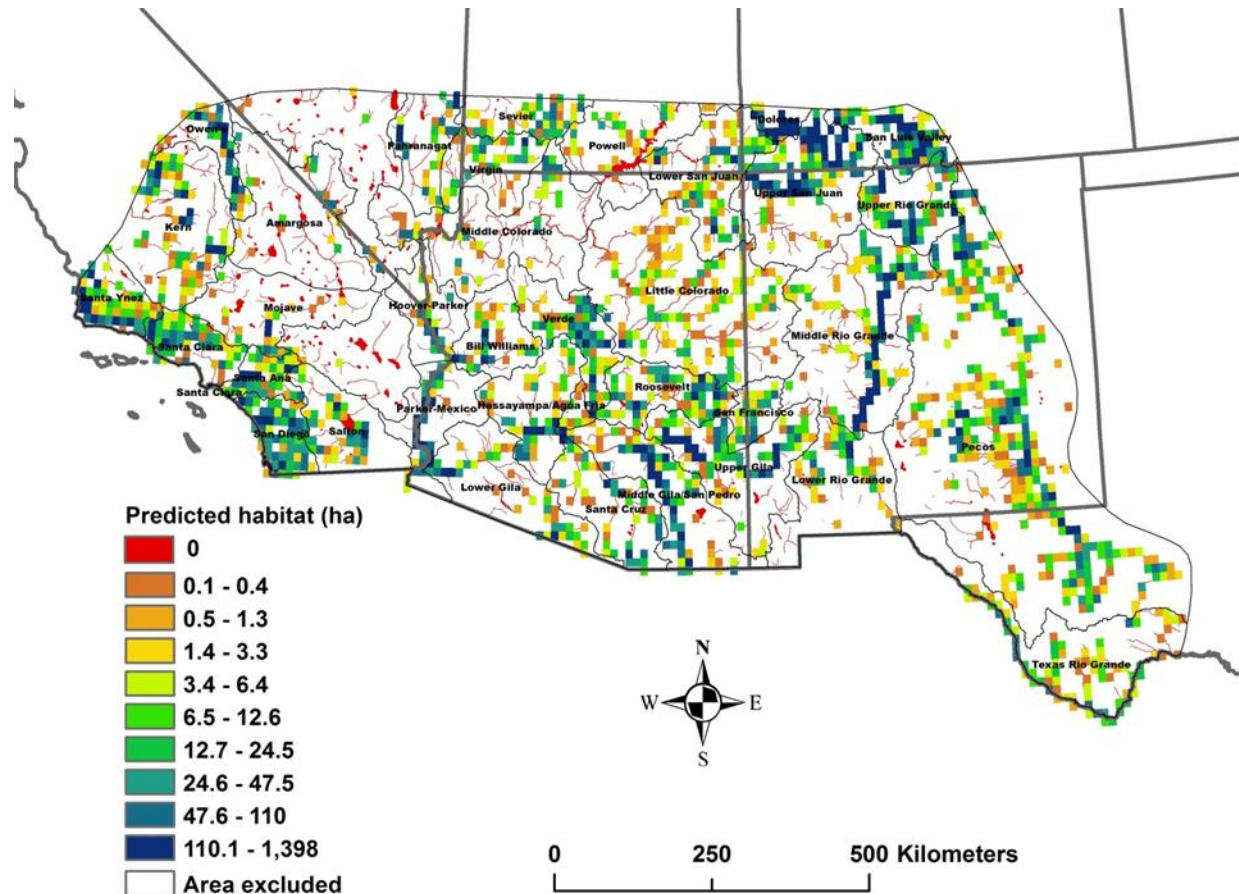

➤ **Yellow-breasted Chat**: low hundreds of pairs

➤ **Southwestern Willow Flycatcher**: <5 known breeding pairs?

➤ **Yellow-billed Cuckoo** : unknown # of breeding pairs

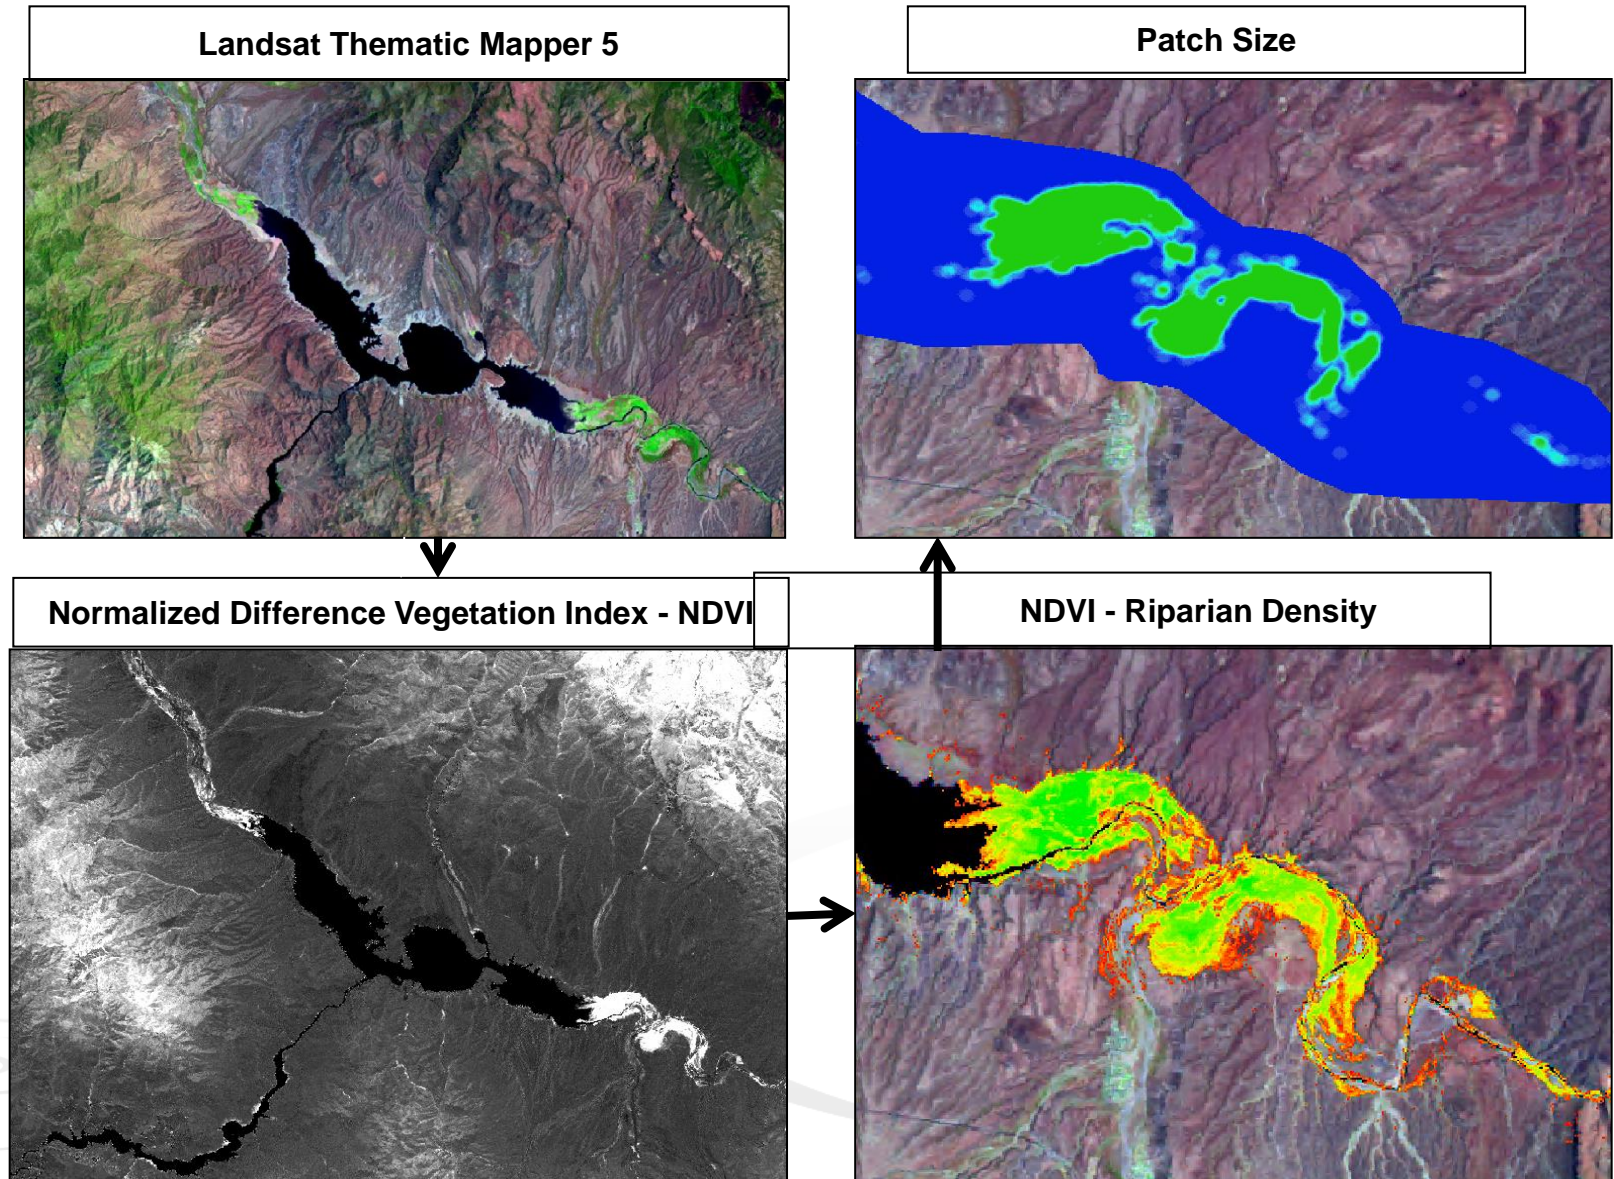

Use published satellite models to predict flycatcher and yellow-billed cuckoo habitat

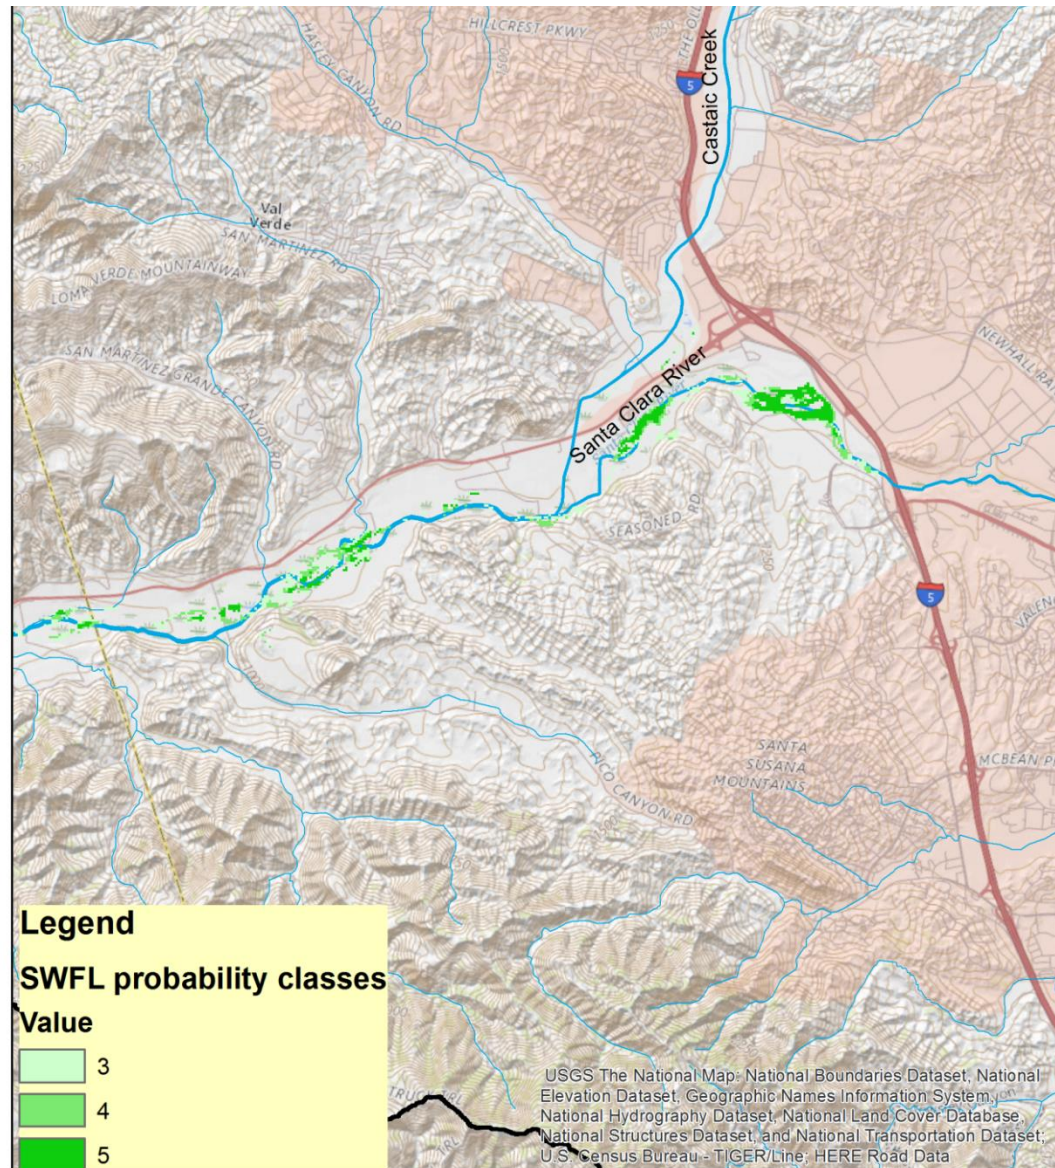

USGS Open-File Report 2016---1120. A Satellite Model of Southwestern Willow Flycatcher (*Empidonax traillii extimus*) Breeding Habitat and a Simulation of Potential Effects of Tamarisk Leaf Beetles (*Diorhabda* spp.), Southwestern United States

Significant predictor variables in flycatcher model: Roosevelt Lake, AZ

Applying satellite model to Santa Clara River

New version of satellite model runs in Google Earth Engine using JavaScript

32-year habitat time series for Southwestern Willow Flycatcher along Santa Clara River calculated with the satellite model

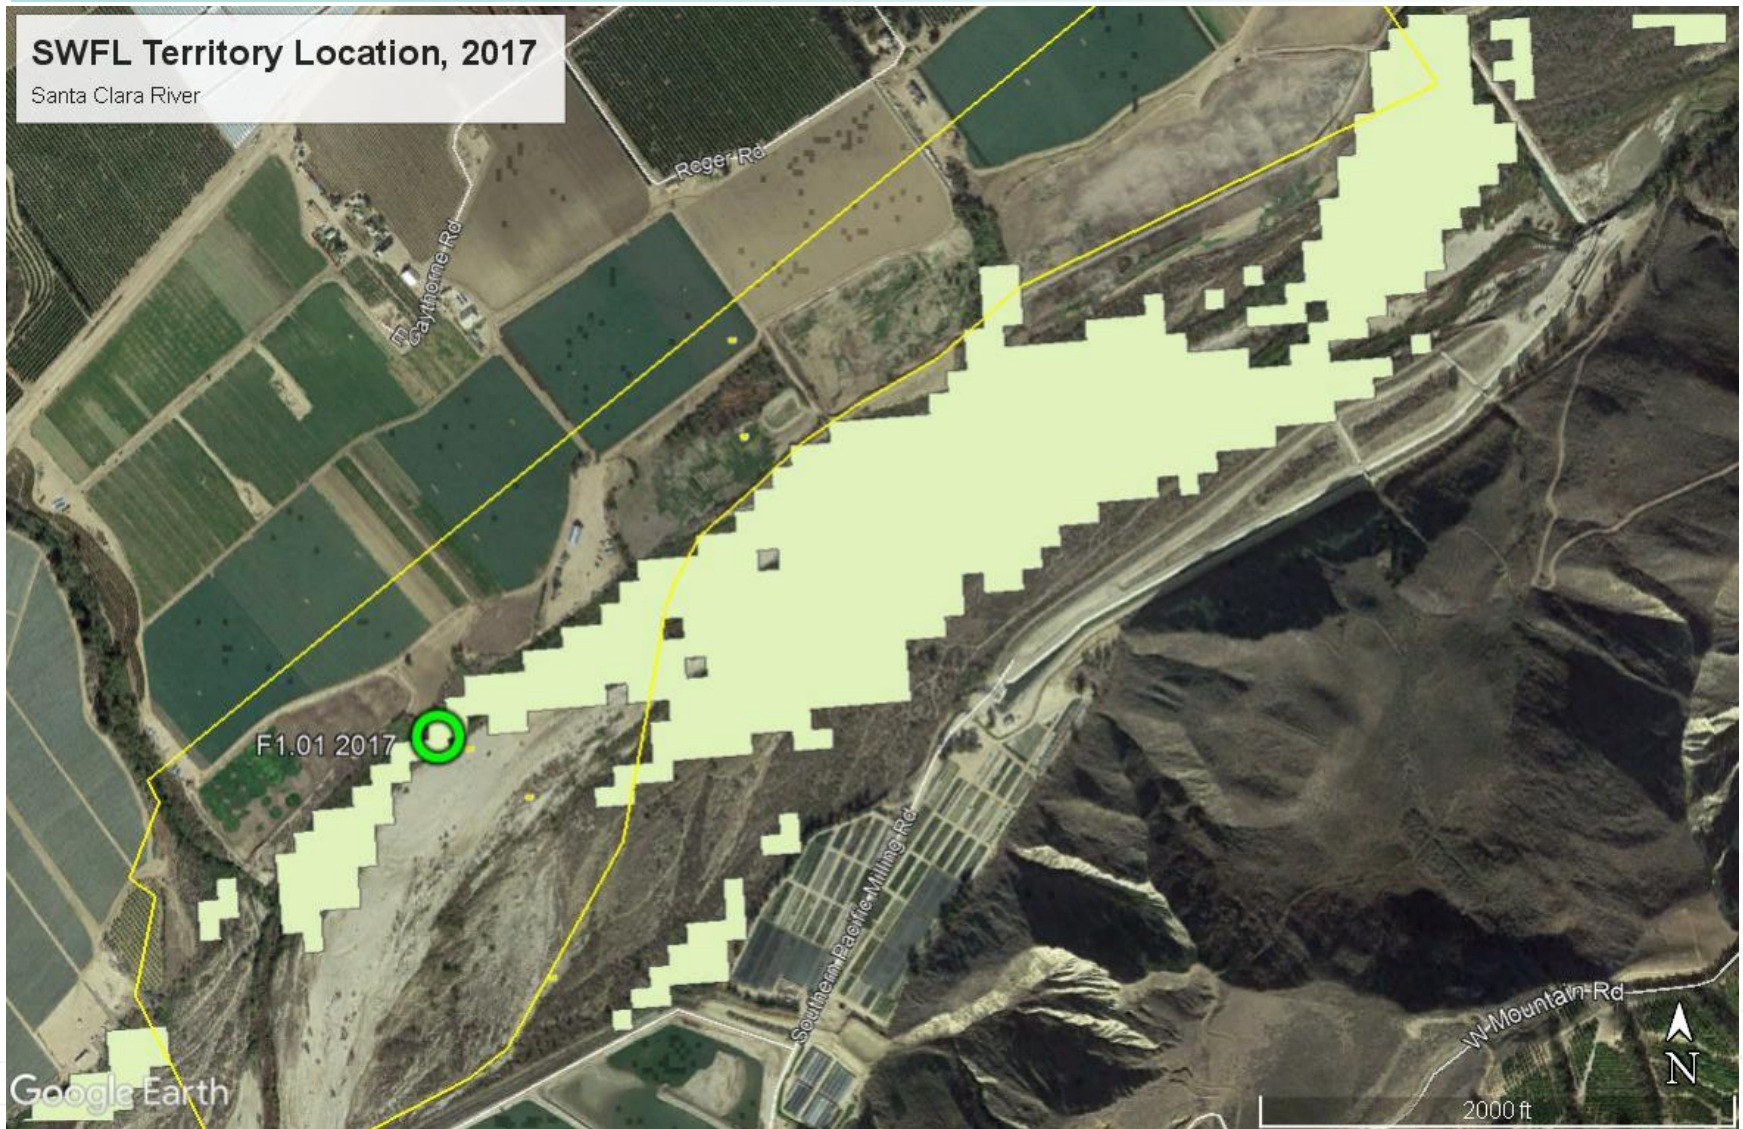

Initial examination of temporal variation in predicted amount of suitable SWFL habitat along the Santa Clara River seem to match well with known timing of flood disturbance (e.g., the 2005 El Nino flood event) and pronounced drought (2014-2016)

32-year habitat time series for Southwestern Willow Flycatcher along Santa Clara River calculated with the satellite model

Initial examination of temporal variation in predicted amount of suitable SWFL habitat along the Santa Clara River seem to match well with known timing of flood disturbance (e.g., the 2005 El Niño flood event) and pronounced drought (2014-2016)

SWFL Modeled Suitable Habitat and Observed Territory in 2017

The General SWFL Model appear to do a good job of predicting suitable habitat based on the few known nest site locations from past years. The model is already proving to be a useful tool for designing river corridor scale survey & monitoring efforts. Next steps include calibrating the model with local bird data and using LIDAR-derived canopy height data to improve model performance

VEGETATION & HABITAT STRUCTURE

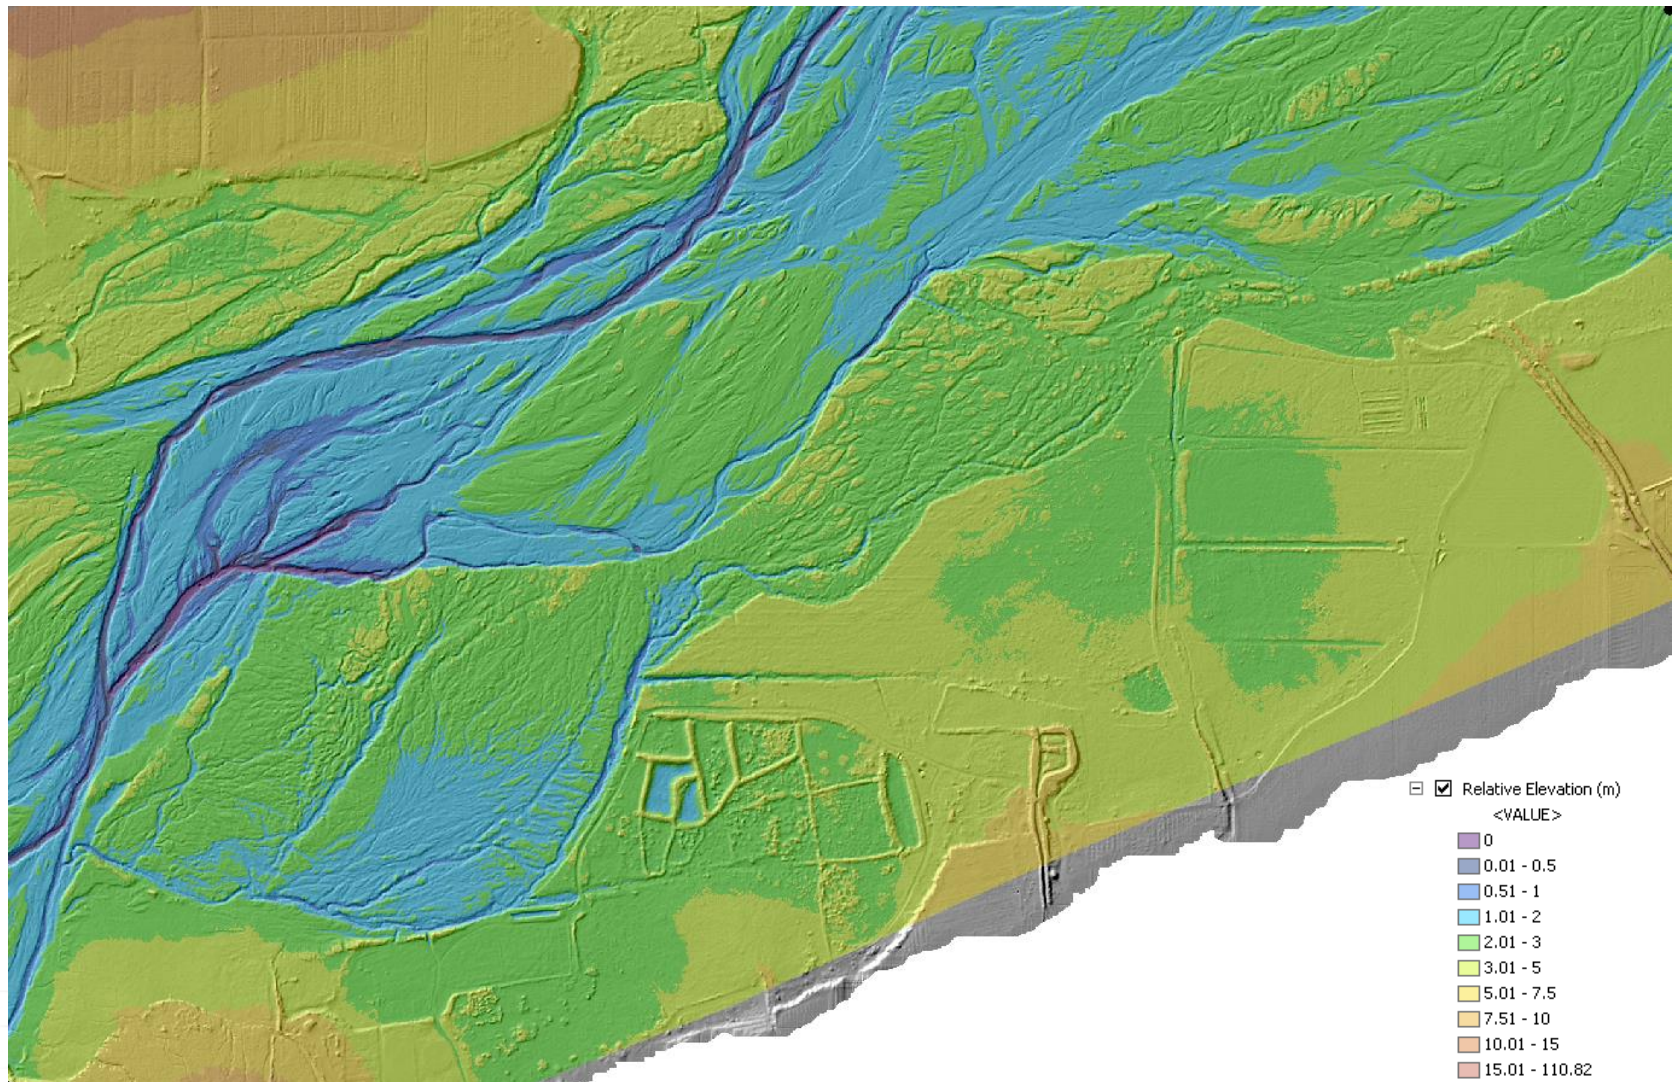

- NCALM high density LiDAR data collected in October 2015
- Habitat Modeling for Least Bell's Vireo, Southwestern Willow Flycatcher, and Yellow-billed Cuckoo

LIDAR Examples from East Grove Riparian Forest

LIDAR Products: Topography and Relative Elevation

Relative elevation (height above river low flow water surface) is useful for identifying geomorphic landforms and can be used as an indicator of expected depth to groundwater and potential for establishment of various riparian plant species

LIDAR Products: Canopy Height

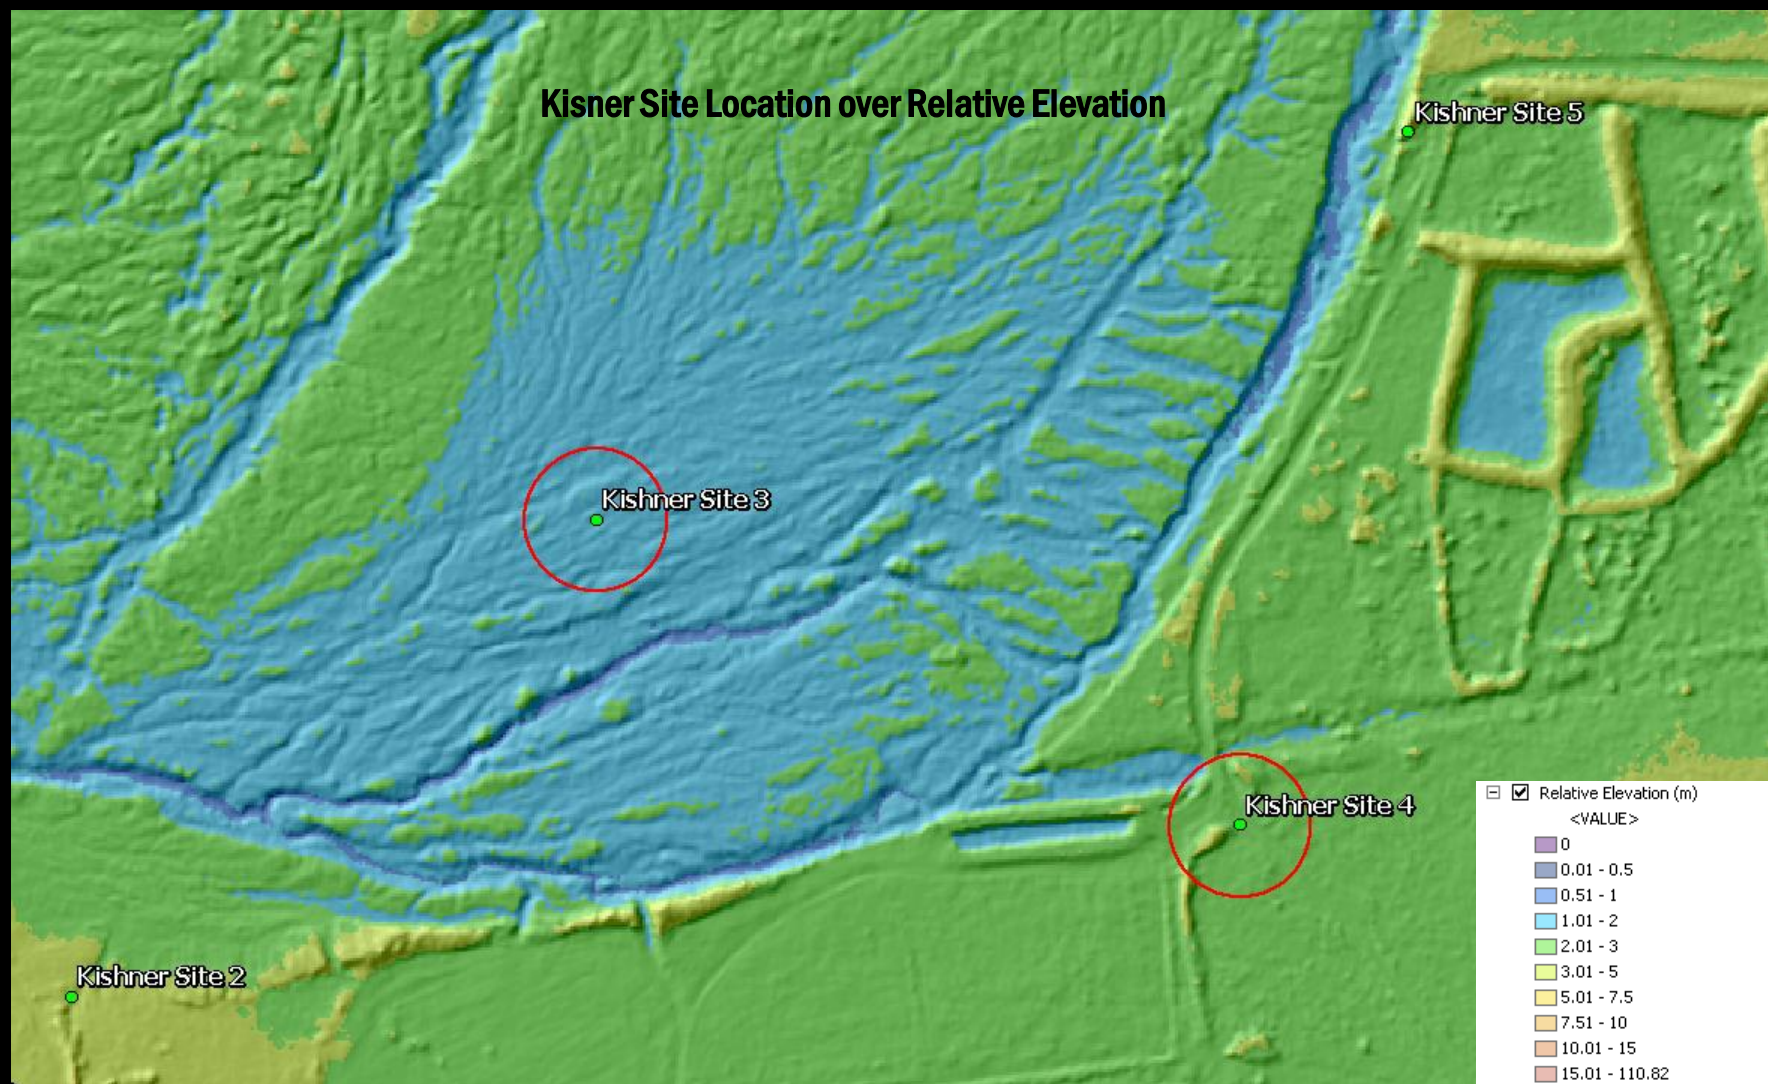

Canopy height of individual trees and vegetation stands can be derived from LIDAR point cloud data

NEXT STEPS

1. Collect ground-truth data on vertical structure using 'stacked cube' method
2. Compare LIDAR and stacked cube data
3. Conduct second year (2019) of breeding season surveys for SWFL and YBCU continue LBVI and general point count surveys
4. Assess habitat structure associated with known nest sites of least Bell's vireo, southwestern willow flycatcher, and yellow-billed cuckoo
5. Use local data to calibrate existing or create new habitat suitability models to guide restoration and monitoring
